

Core GPT Team Overview: This image shows the main GPTs utilized in the SAT program. Each member of the virtual team is tuned or tasked for specific roles: theoretical formulation, debugging, hypothesis stress-testing, or narrative simulation. These GPTs collaborate iteratively to refine SAT's logic and address internal inconsistencies.

Instances of ChatGPT in Use: Here, we see the range of projects and variant sessions within ChatGPT, showing compartmentalized sessions for development (ActiveEdge), analysis, and experimental prompt branches (including vNext and retired Theorizer sessions).

SAT-Naive GPT (Example 1): An early control interaction with a non-SAT-trained ChatGPT. It correctly identifies SAT as a non-standard or emerging theory and offers speculative expansions on what SAT might mean based on acronym analysis.

Given the equation:

$(A - B)/B = (C - D)/D$

Solve for C, using the following values:

A: 73.0
B: 67.4
D: 299792.458

Once solved, calculate the percent difference between C and D.

We are given the equation:

$$\frac{A - B}{B} = \frac{C - D}{D}$$

We are to solve for C using:

- A = 73.0
- B = 67.4
- D = 299792.458

Step 1: Plug in the known values:

$$\frac{73.0 - 67.4}{67.4} = \frac{C - 299792.458}{299792.458}$$

Calculate the left-hand side:

$$\frac{5.6}{67.4} \approx 0.08310178$$

Now solve for C:

$$\frac{C - 299792.458}{299792.458} = 0.08310178$$

Multiply both sides by 299792.458:

$$C - 299792.458 = 0.08310178 \times 299792.458 \approx 24906.230$$

Consider this equation

$$1 + z = (m_{e_emitted}) / (m_{e_observed})$$

Definition of Terms:

z — Cosmological redshift, traditionally defined as the fractional increase in the wavelength of light from distant sources.

$m_{e_emitted}$ — The effective electron mass at the location and time the light was emitted (in the emitter's local tension field).

$m_{e_observed}$ — The effective electron mass at the location and time of observation (in the observer's local tension field).

This equation presents a **non-standard interpretation** of cosmological redshift, where the redshift z is expressed not in terms of wavelength or scale factor, but instead as a ratio of **effective electron masses** in different gravitational or tension field environments:

$$1 + z = \frac{m_{e_emitted}}{m_{e_observed}}$$

Interpretation

In standard cosmology, redshift z is defined as:

$$1 + z = \frac{\lambda_{observed}}{\lambda_{emitted}} = \frac{a_{now}}{a_{then}}$$

where a is the scale factor of the universe. However, the equation you provided implies that **variations in the effective electron mass** due to different local fields (e.g. gravitational potential, tension field, or another scalar field) could cause spectral line shifts that mimic redshift.

Conceptual Foundation

This formulation suggests:

- The **emission frequency** of atomic transitions depends on the local effective electron mass m_e , because atomic energy levels scale with it.
- If the electron mass varies with spacetime location due to some physical field (like a varying scalar field or gravitational effect), then photons emitted with a certain energy at one location could be interpreted

ChatGPT can make mistakes. Check important info.

SAT-Naive GPT (Example 3): In this instance, SAT-naive GPT attempts to construct a unified physical theory based solely on prompts emphasizing simplicity and conceptual unity. While speculative, it exhibits significant overlap with SAT's emergent geometry motifs.

SAT-Naive GPT (Example 4): Here the model produces elegant unification hypotheses without prior exposure to SAT: one of several experiments to validate the independent plausibility of SAT-style frameworks arising spontaneously under minimal-assumption constraints.

SAT-Naive GPT (Example 5): A strong example of 'convergent emergence'-the GPT, asked to explain cosmological redshift through mass variation, generates a compatible angle with SAT's stress-based redshift interpretations, unprompted by prior definitions.

SAT-Naive GPT (Example 6): Fusion domain wall analysis without SAT context. Yet the model recreates analogous structures to SAT's twist sector boundary behaviors, including domain-localized excitations. Used as a blind validation of SAT's predictive naturalism.
